1. INTRODUCTION

1.1 OBJECTIVE

This is a summary of an Energy Engineering Analysis, conducted to provide a Basewide Energy Savings Plan at Fort Pickett, Virginia. This Plan includes recommendations for energy conservations Projects to reduce the installation's present energy consumption, as well as a description of other energy-related factors which affect consumption. It is important to note that savings figures presented in this summary can only be realized after all Projects have been implemented. MMM Design Group has developed Projects that meet the funding requirements for the D.O.D.'s Energy Conservation Investment Program. Furthermore, the recommended Projects provide compliance with the Army Facilities Energy Plan. This summary presents data relative to the following chronological period:

- A. 1975 Energy Consumption (baseline).
- B. 1985 Energy Use (projection).

1.2 METHODOLOGY

The Analysis methodology was based in part on an examination and study of a "sampling" of structures representative of all of the structures at Fort Pickett. These "sample" or "study" buildings were used to model "building use groups" which had similar architectural, mechanical, and electrical system characteristics, as well as similar functional uses. These characteristics are summarized in Figures 1, 2, and 3.

2. EXISTING ENERGY CONSUMPTION

Once these building group system characteristics were determined, they were input into the Corps of Engineers Building Loads Analysis and Systems Thermodynamics (BLAST) Program. Then, the BLAST Program parameters were manipulated in order to simulate 1975 conditions. See Building Group Energy Usage (Figure 4) for a description of energy sources, and energy use totals by building group. Finally, a total was prepared to model actual MBTU consumption record consumption between 1975 and 1980, adjusted for historic degree days, (Figures 5). These figures reflect a total consumption of 168,999 MBTU for the 1975 baseline, including energy use for on-base buildings, Reserve Centers and all other energy consuming systems (site utilities, site lighting, etc.).

Figures 6A through 6C illustrate the relative percentages of fuel types used during the 1980 fiscal year. Noteworthy is the fact that electricity and fuel oil make up the largest portions of the consumed energy mediums, comprising 47% and 44% respectively. The remaining fuel types include LP and natural gas at 8% and kerosene at 1%.

Figures 7A through 7C indicate the annual source energy consumed by each of the significant building groups used in the energy model, and compare this consumption with the building group area. Housing is the largest user, consuming 27% of total energy, administrative the second largest consumer on-base at 20%, and shops consume 15%. Recreation and dining facilities use 10% and 7% respectively. Utilities use approximately 4%. Off-base reserve centers are the second largest overall user at 20%.

3. ENERGY CONSERVATION MEASURES DEVELOPED

3.1 Introduction

The tool used for initial analysis of possible new energy conservation measures or options at Fort Pickett was a Preliminary Matrix (Figure 8). This matrix ranked each option by building use group, and established priorities for detailed study and project development of selected options.

The separately bound "Appendix" volume of this Energy Engineering Analysis provides documentation of the back-up material developed during the course of the work. The results of the programmed energy conservation Projects are included in the separately bound volume entitled "Project Documentation." A summary of all Projects, categorized by EEA study Increment, can be found in the EEA Project Summary (Figure 9). These projects are listed in order of their E over C Ratio.

3.2 RECOMMENDED ENERGY CONSERVATION PROJECTS: INCREMENTS (A) AND (B)

A total of nine (9) projects, Increments (A) and (B), qualified under ECIP criteria as programmable energy conservation projects for on-base facilities. Included are the installation of ceiling fans for atmospheric destratification as well as noncombustable insulation for domestic water heaters and building envelopes. Also qualifying for these Increments are the replacement of inefficient oil burners, boilers and light fixtures, and the installation of night setbak thermastats and a basewide Energy Management Control System.

In addition several projects qualified for Increment (A) for off-post reserve centers. Included are the installation of thermostats for night setback, minimum occupancy heating and cooling units, weatherstripping, caulking and ceiling insulation.

3.3 RECCOMENDED ENERGY CONSERVATION PROJECTS: INCREMENT (G)

A total of five (5) Projects did not meet the necessary ECIP criteria, and therefore do no appear in the Project Documentation volume of this report. These projects were subsequently classified under Increment (G). Included under this increment are the installation of storm windows, weatherstripping and caulking, timer switches for toilet room lighting, domestic water heater controls, and wall insulation for CMU walls.

3.4 RECOMMENDED ENERGY CONSERVATION PROJECTS: INCREMENT (C)

Several options were analyzed for potential renewable energy projects (Increment C). Included in this part of the study is a solar domestic water heating system, an active solar application. Trombe wall adaptations are presented as a passive solar application. Additionally, biomass fuel potential at the Fort is evaluated. None of the options analyzed qualified for ECIP funding.

3.5 RECOMMENDED ENERGY CONSERVATION PROJECTS: INCREMENT (F)

Recommendations for modifications to system operation at Fort Pickett, which are within the funding authority and/or management control of the Facilities Engineer, fall into four broad categories.

- A. Replacement of "as-needed" system components with "state-of-the-art", high-efficiency components: Such components as electrical lamps, water system pump motors, and high-bay roll-up doors, are examples of opportunities to save energy by means of Facility Engineer selection and purchase proceedures.
- B. Elimination of unnecessary energy consuming items:
 This proposal requires coordination with current and
 programmed building use. It involves the
 elimination of domestic hot water in Administration
 buildings, the reduction of window glazing where not
 required for natural light, ventilation or egress,
 and the reduction of lighting levels to minimum
 standards.
- C. Controls of energy systems: This suggestion includes miscellaneous installations of photocell and time clock controls for lighting, selective switching of lighting and domestic hot water circulating pump controls.
- D. Future Metering Plan: Provided for the future monitoring of electricity consumption, this plan determines the high energy use buildings on base and suggests locations for future electrical meters.

The above recommendations are discussed in more detail within the body of the Report Narrative.

4. ENERGY AND COST SAVINGS

The annual energy savings by proposed Project are given in Figures 9, along with the payback period, in years. This payback is based on the implementation of all Projects by fiscal year 1985, and uses fuel types related to each respective project. Fuel cost escallation is given from 1980 to 1985 in Figure 10, entitled "Energy Cost Projection."

For projected energy consumption and total energy savings to be realized, savings from inter-related or interdependent projects must be coordinated. Thus, the total energy savings, as shown in the Energy Projection Summary (Figure 11), is based on the assumption that all projects will be implemented by a given fiscal year (1985).

5. ENERGY PLAN

A Fort Pickett Basewide Energy Savings Plan, the ultimate result of this Energy Engineering Analysis, includes energy use input from the following:

- A. Past Energy Conservation Projects.
- B. Energy Conservation Projects Under Contract.
- C. Operational and Maintenance Projects.
- D. Demolition and Shutdown.
- E. New Construction Projects.
- F. Recommended Energy Conservation Projects.

A summary of the above energy use factors is given in Figure 11, the Energy Projection Summary, with the exception of Increment C and Increment G energy savings, as well as savings from several Increment F projects which could not be projected. (See Figure 9).

As a result of total inplementation of the Fort Pickett Basewide Energy Savings Plan, energy usage per square foot of building area will be reduced by over 20%. This reduction of energy usage per square foot shall equate approximately to the following:

- A. FY 1975 BTU/square foot = 72,000.
- B. FY 1985 BTU/square foot = 57,000.

See Section 3 of the Appendix for Back-up calculations of these figures.

Past and ongoing energy conservation projects, along with those projects recommended by this Energy Engineering Analysis, account for a 31% reduction in FY 1975 energy consumption. However, the sum of new construction and decreased winterization results in a 18% increase in energy consumption. This increase severly reduces the impact of the savings achieved by energy conservation projects. The final result of the savings plan, as seen in Figure 11, is an overall 13.0% decrease in annual energy consumption by FY 1985.
